Methods of parameter estimation

| Distribution | Parameters |
|--------------|--------------------------|
| normal | mean, standard deviation |
| Poisson | mean |
| Student's t | degrees of freedom |
| Weibull | shape, scale |
| lognormal | mean, standard deviation |
| exponential | rate |
| uniform | minimum and maximum |
| logistic | location, scale |
| etc. | |

- ✦ Method of Moments (MoM)
- ✦ Maximum Likelihood Estimate (MLE)
- ✦ Bayesian estimation
- ✦ Method of Least Squares
- ✦ etc.

Maximum Likelihood Estimate (MLE) for one parameter

Definition

If random variables have joint probability $p(x_1, x_2, \dots, x_n | \theta)$ then the function $L(\theta | x_1, x_2, \dots, x_n) = p(x_1, x_2, \dots, x_n | \theta)$ is called the **likelihood function** of θ .

The **likelihood function** tells the probability of getting the data that were observed if the parameter value was really θ .

Definition

The **maximum likelihood estimate** of a parameter θ is the value that maximizes the likelihood function $L(\theta | x_1, x_2, \dots, x_n) = p(x_1, x_2, \dots, x_n | \theta)$.

In practice they maximize the logarithm of the likelihood function and solve the following equation: $\frac{d \log L(\theta | x_1, x_2, \dots, x_n)}{d\theta} = 0$

Maximum Likelihood Estimate (MLE) for μ in normal distribution when $\sigma=1.3$

Given a sample: 4.2 5.2 5.6 6.1 7.3 8.5 and population standard deviation $\sigma=1.3$, estimate μ .

The log-likelihood function (its first derivative) is zero at the maximum likelihood estimate. The estimated μ is 6.15

Maximum Likelihood Estimate - standard error

The following formula can find an approximate numerical value for the **standard error** of almost any maximum likelihood estimator: $se(\hat{\theta}) \approx \sqrt{-\frac{1}{l''(\hat{\theta})}}$

Reminder: standard error is the standard deviation of the estimator.

For the 95% confidence interval we can write:

$$\hat{\theta} - 1.96 \times se(\hat{\theta}) < \theta < \hat{\theta} + 1.96 \times se(\hat{\theta})$$

For the 90% confidence interval we can write:

$$\hat{\theta} - 1.645 \times se(\hat{\theta}) < \theta < \hat{\theta} + 1.645 \times se(\hat{\theta})$$

Maximum Likelihood Estimate - exponential distribution (1)

The probability density function (pdf) of exponential distribution is $\lambda e^{-\lambda x}$, $x \geq 0$ (0 otherwise). **We want to estimate parameter λ .**

Likelihood function: $L(\lambda|x_1, \dots, x_n) = \lambda^n e^{(-\lambda \sum x_i)}$

Log-likelihood function: $l(\lambda|x_1, \dots, x_n) = n \log(\lambda) - \lambda \sum x_i$

MLE (find point estimate): $l'(\lambda|x_1, \dots, x_n) = \frac{n}{\lambda} - \sum x_i = 0$, so $\hat{\lambda} = \frac{1}{\bar{x}}$

Standard Error: $se(\hat{\lambda}) \approx \sqrt{-\frac{1}{l''(\hat{\theta})}} = \frac{\hat{\lambda}}{\sqrt{n}} = \frac{1}{\sqrt{n\bar{x}}}$ (where $l''(\lambda) = -\frac{n}{\lambda^2}$)

95 % confidence Interval for λ : $\frac{1}{\bar{x}} \pm 1.96 \times \frac{1}{\sqrt{n\bar{x}}}$

Maximum Likelihood Estimate - exponential distribution (2)

The table shows the number of operating hours between successive failures of air-conditioning equipment in ten aircrafts.

Assume that each aircraft has the same failure rate and the occurrence of a failure in any hour is independent of whether or not the equipment has just been repaired.

The failures are a Poisson process with rate λ per hour for each aircraft and can be modeled by an **exponential distribution**.

Maximum Likelihood Estimate - exponential distribution (3)

The mean time between failures of the 199 air-conditioners is $\bar{x} = 90.92$ hours.

The MLE for the estimated failure rate λ is $\frac{1}{\bar{x}} = 0.0110$ failure per hour.

95% confidence interval for the failure rate:

$\frac{1}{\bar{x}} \pm 1.96 \times \frac{1}{\sqrt{n\bar{x}}} = 0.00974$ to 0.01253 failures per hour, i.e.
between 9.47 and 12.53 failures per thousand hours of use.

Maximum Likelihood Estimate (MLE) for two parameters

Given a sample, we can estimate two unknown parameters in a probability distribution, for example, estimate parameters μ and σ in a normal distribution.

Definition

If random variables have joint probability $p(x_1, x_2, \dots, x_n | \theta, \phi)$ then the function $L(\theta, \phi | x_1, x_2, \dots, x_n) = p(x_1, x_2, \dots, x_n | \theta, \phi)$ is called the **likelihood function** of θ and ϕ .

The likelihood function is maximised at a turning point of the likelihood function and could therefore be found by setting the partial derivatives of $L(\theta, \phi)$ with respect to θ and ϕ to zero.

Using MLE method with partial derivatives, it is also possible to estimate three and more unknown parameters, if required.

Maximum Likelihood Estimate - major properties

There are two important properties of the maximum likelihood estimator $\hat{\theta}$ of a parameter θ based on a random sample of size n from a distribution with a probability function $p(x_1, x_2, \dots, x_n | \theta)$:

- ✿ Asymptotically **unbiased**: $E[\hat{\theta}] \rightarrow \theta$ when $n \rightarrow \infty$
- ✿ Asymptotically has a normal distribution: $\hat{\theta} \rightarrow \text{normal}$ distribution when $n \rightarrow \infty$ that can be used to generate **confidence intervals**.
- ✿ Maximum likelihood estimators have **low mean squared error** if the sample size is large enough. MLE can be heavily **biased** for small samples!

MATLAB uses MLE as a default method for parameter estimation (`normfit`, `weibfit`, `expfit` etc.).

Continuous distributions (1)

The **lognormal distribution** is used in situations where values are positively skewed, for example, for financial analysis of stock prices. Note that the uncertain variable can increase without limits but cannot take negative values.

Lognormal distribution

In the **beta distribution** the uncertain variable is a random value between 0 and a positive value and. The distribution is frequently used for estimating the proportions and probabilities (i.e. values between 0 and 1). The shape of the distribution is specified by two positive parameters.

Continuous distributions (2)

The **Student's t distribution** is the most widely used distribution in confidence intervals and hypothesis testing. The distribution can be used to estimate the mean of a normally distributed population when the sample size is small. The t-distribution comes to approximate the normal distribution as the degrees of freedom (or sample size) increases.

The **chi-square distribution** is usually used for estimating the variance in a normal distribution.

Continuous distributions (3)

In a homogeneous Poisson process with rate λ events per unit time, the time until the first event has a distribution called an **exponential distribution** (see example in the previous slides). All exponential distributions have their highest probability density at $x = 0$ and steadily decrease as x increases.

Typical question: "How long will it take till...".

Continuous distributions (4)

The **Weibull distribution** can be used as a model for items that either deteriorate or improve over time. It's basic version has two parameters: shape (α) and scale (β .)

- ✿ $\alpha > 1$ - the hazard function is increasing so the item becomes less reliable as it gets older.
- ✿ $\alpha < 1$ - the hazard function is decreasing so the item becomes more reliable as it gets older.
- ✿ $\alpha = 1$ - the hazard function is constant so the lifetime distribution becomes **exponential**.

Typical question: "How long till something fails, assuming that ...".
